SOURCES

~600

PAGES OF INTERNAL
WORKING NOTES

8

DAYS FROM KICKOFF
TO SYNTHESIS

Research-first consulting, machine-readable on delivery. **Fast, narrow, fully cited.** Priced as a research deliverable — not as a strategy engagement.

WHAT YOU CAN COMMISSION TODAY STANDALONE RESEARCH REPORTS

01 · CONSTRAINT MAP

Operating-problem decomposition
A real problem (digital accuracy, automation, format efficiency) decomposed against peer benchmarks. Addressable-value math, peer playbooks, pre-registered failure criteria.

02 · OPTION PAPER

Operating-model option-mapping
Three-option organizational comparisons with fit-to-context analysis: governance posture, capex envelope, talent market, peer precedent.

03 · INDUSTRY DEEP-READ

Peer-set benchmark synthesis
A specific peer set, a specific operational dimension, fully sourced. The artifact a CFO would commission a McKinsey study for — delivered in days.

04 · DECISION SYNTHESIS

Inputs / options / consequences
A single live decision framed as inputs, options, and downstream consequences — with the underlying evidence cited inline.

WHERE IT MIGHT GO FROM HERE OPTIONAL · TBD

Standing research relationship TBD
Periodic refresh of an evolving knowledge base, indexed to your strategic priorities.

Embedded fractional engagement TBD
Same research-first methodology applied continuously across a single function.

Fractional CIO / strategy bridge TBD
Time-bounded chair of an innovation portfolio, with permanent staffing as the exit.

WHY USE IT
Built to clear the bar that traditional consulting fails on routine questions. The frame is "is this question worth \$X to answer" — not "do we have the budget for a strategy project."

HOW IT COMPOUNDS
Every output is a fully-cited document *and* machine-readable. Paste it into your LLM; query it indefinitely. **The research compounds rather than expires.**

SOURCE CORPUS

14 deep research threads + 3 supplementary focus dossiers · 480+ cited sources · ~600 pages of internal working notes

STATUS

Standalone synthesis — not a proposal

How To Read This

This document is a synthesis. The full corpus behind it is large enough that a verbatim read is the wrong way to use it. I would skim the executive summary, jump to whichever of the seven binding constraints is most contested, and come back to team architecture at the end. The pages on the test kitchen — vectors, capex envelope, kill gates — are written to be useful inside a charter conversation if you decide to commission one.

Numbers cited in the body are pulled from public filings, peer earnings calls, vendor disclosures, and trade-press reporting from 2022–2026. Where Panda data is inferred from public proxies, I have flagged the inference. Where the source thread goes deeper than the page allows, I have pointed to it (DR-XX, SFDR-XXX) so you can ask for the underlying material at any depth you want.

The corpus is alive. If a single paragraph here is doing more work than you want to verify, that paragraph has somewhere between five and forty pages of underlying research that produced it.

Executive Summary

The function you are standing up is the right venue, at the right moment, for a portfolio of operational gaps that are individually solvable and collectively worth high hundreds of millions of dollars annually. The work is real. The peer playbook on parts of it is mature; on the wok side, no peer has solved it yet, which is why the program matters.

\$80–135M

ANNUAL COST HIDDEN IN DIGITAL ORDER ACCURACY

\$2.7B digital revenue × an estimated 3–5 pp gap to peer best-in-class. The largest fixable opportunity in the portfolio. Single-fiscal-year deliverable.

\$200M

PAW INVESTMENT SCALE, PEER-VALIDATED AT ZERO SCALE

No peer — Chipotle, Sweetgreen, Miso, McDonald's, Chinese vendor ecosystem — has validated wok automation commercially. PAW is original R&D, not a capex purchase.

\$795M–\$1.34B

COMBINED ADDRESSABLE MARGIN POOL, 20-STATEMENT PORTFOLIO

Half is concentrated in five problems: labor productivity, digital accuracy, wok standardization, digital economics, format capital efficiency.

3.6x

SG&A RATIO GAP TO CHIPOTLE (STRUCTURAL, NOT SOLVABLE HERE)

8–10% vs. 4.2%. Mostly the cost of the 100% company-operated model. Innovation moves restaurant-level margin instead, unlocking \$65–130M of absolute profit pool.

3 / 4 / 1+3

TEST KITCHEN ARCHITECTURE: VECTORS / GATES / SITES

3 validation vectors (wok, digital accuracy, drive-thru). 4 gates with pre-registered kill criteria. 1 controlled test kitchen + 3 instrumented control stores. Sections 6–7.

The single substantive recommendation in this document — the rest is observation, benchmark, and option-mapping — is on team architecture. Staff for execution and for portfolio coordination, not just one. A small permanent core (program lead, test kitchen GM and Kitchen Director, data lead) paired with fractional or part-time strategy capacity through the first 6–12 months. Make permanent the parts that prove themselves; do not pre-commit to a permanent shape until the data is in. Section 8 details the capability mix, the sequence, and the cross-functional mechanisms that give the team traction on dependencies that sit outside the CDO mandate.

The Operating Premise

§ 02

Why a coordinated portfolio, and why now

Panda's existing innovation model is not an accident. It mirrors what every QSR at \$1B–\$3B in system sales runs — local autonomy, ops-led optimization, function-by-function tech investment. Below ~\$3B, this scales. The decision velocity of a competent functional executive is faster than any committee, and the dollar value of the missed dependencies is smaller than the cost of governance overhead.

The threshold at which this starts to break is empirically visible across the QSR set. Chipotle elevated cross-functional technology authority around \$5B in revenue (Curt Garner promoted to CTO/CDO in 2015). Starbucks built the Tryer Center at ~\$24B in revenue (announced 2018), but the predecessor structure predated it by a decade. McDonald's Speedee Labs has been the equipment-and-format R&D function since 2005 and was rebuilt in 2018. CFA's Innovation Center opened in 2019. Domino's centralized digital under the CEO around 2010 at ~\$1.5B in revenue.

The pattern: every large-scale QSR that compounded over a decade put a coordinating function in seat by the time it reached Panda's current scale. Several put it in seat well before. The exceptions are not in the comp set anymore. Boston Market is the most often cited; the cautionary detail is that the strategic problems Boston Market failed to coordinate on (digital, format, kitchen ops) are exactly the surface area where Panda's portfolio currently sits.

This is not a claim that Panda is at structural risk. It is a claim that the marginal cost of an uncoordinated portfolio at this scale is real and quantifiable. Per the Phase 2 problem portfolio, the cumulative concept-to-pilot delay caused by ambiguous ownership is conservatively 12–18 months on initiatives that should be moving in 6–9. At a portfolio addressable value of ~\$800M, that delay carries an opportunity cost in the \$30–80M range annually (DR-03, DR-18).

The four largest unowned dependencies

The cleanest restatement of the diagnosis is this: four dependencies in Panda's current innovation footprint do not have a single owner, and the operating leverage on each requires multiple functions cooperating.

01

Wok automation

CAPITAL PLANNING • OPERATIONS • STORE DESIGN

PAW investment (\$200M signal) sits between operations and capital planning. The labor productivity story it unlocks lives in operations. The cook-line workflow redesign it implies lives in store design.

02

Digital order accuracy

IT / DIGITAL • OPERATIONS • STORE DESIGN

The technology problem (KDS, POS, makeline routing) lives in digital. The operational problem (order data → cook → bag → guest) lives in operations. The format problem (dedicated digital makelines) lives in store design.

03

GridPoint smart building

FACILITIES • OPERATIONS • CAPITAL PLANNING

Energy management is supply-chain-led today. Predictive maintenance is operations-led. Franchisee-facing dashboards are an open question. Capex prioritization against new-unit construction is finance-led.

04

Drive-thru throughput

FORMAT • LABOR • TECHNOLOGY • SOP

No single function can move the cars-per-hour number without three other functions cooperating on format, training, technology integration, and standard operating procedure.

Whatever the form factor, the function being created is portfolio coordination — not innovation invention. Someone has to own the calendar, set the quarterly portfolio, and have authority to call where the next dollar of capex goes. The team you are standing up is the natural home for that work. Format and store design already sit with you; the construction pipeline already sits with you; smart building deployment already runs through your facilities organization. Adding kitchen-side ops innovation, digital accuracy, and drive-thru throughput to the same coordinated portfolio extends the existing reach by adjacency rather than by building a new structure.

Peer Innovation Operating Models

§ 03

The shape of an innovation function is determined by what it is being asked to do. The peers prove this isn't tautological. Eight benchmarks, the structures they chose, and what they shipped:

COMPANY	FUNCTION SHAPE	REPORTS TO	CYCLE TIME	FLAGSHIP OUTPUT	WHAT IT FAILED AT
Walmart	Store No. 8 (incubator), 2017–2024	CEO	Multi-year	Drone delivery, shelf robots	Dismantled Jan 2024; venture model didn't scale
Starbucks	Tryer Center (Seattle, ~20 staff + rotation)	COO → CEO	100-day fast track / 6–18mo equipment	Siren Craft System (1,160 stores)	No food-equipment validation
McDonald's	Speedee Labs (Chicago, ~50 staff, 21K sqft)	EVP Global CIO → CEO	12–24mo food / 18–36mo equipment	Voice AI (twice; Apprente then Google Cloud)	Internal digital builds; multiple resets
Chipotle	Innovation & Technology + Cultivate Center	CTO → CEO	4–12 week pilot waves	Hyphen makeline, Autocado, Chipotlane (700+ stores)	Robotics rollout slower than promised
Chick-fil-A	Embedded across ops + Innovation Center	COO/CEO	Continuous	Drive-thru excellence; franchise alignment	No standalone breakthrough innovation
Sweetgreen	Acquisition-driven (Spyce → Infinite Kitchen)	Chief Ops/CEO	Acquisition cycles	Infinite Kitchen (~7 stores, \$60K+/day)	Margin still negative at parent level
Taco Bell	Live Más Ventures + Defy team	Chief Product & Growth	Variable	Defy autonomous ghost kitchen	Capex per unit very high; small footprint
Domino's	Embedded under CEO	CEO direct	Continuous	Pizza Tracker; AI order prediction; autonomous delivery	International digital lag

LESSON 01

The successful long-cycle innovations are **infrastructure, not robotics**. Chipotle's biggest move in a decade was the second makeline — entirely human-staffed, drove peak throughput from ~80 to 120+ orders/hour. Starbucks' biggest move was Siren Craft, an espresso-workflow redesign with no robot. Robotics is a longer-cycle bet that may pay off but should not anchor the operating-margin story.

LESSON 02

The **venture-incubator model has lost**. Walmart Store No. 8 was the most ambitious centralized retail innovation org ever built and was wound down January 2024. The work it produced couldn't be transferred into the operating business at the velocity the operating business needed. Starbucks Tryer never set up that way — partner rotation pulls the operating business through Tryer, instead of pushing innovation out.

What is not in the comp set: a wok-cooking peer

Worth stating bluntly because it shapes everything downstream. There is no peer in the comp set that has solved Panda's specific kitchen problem. Starbucks does not validate hot food equipment. Chipotle's makeline robotics are laminar-flow assembly (bowls, salads). Sweetgreen's Spyce automation is bowl-class. McDonald's Speedee Labs has done extensive flat-top grill and fry work — no wok work. The Chinese vendor ecosystem that does claim wok automation has zero verified commercial QSR deployments outside of restricted Chinese-market deployments that cannot be independently validated.

The implication is structural. On wok, Panda is at the front of the curve, not the back. PAW is not a "buy and deploy" problem. It is original applied R&D, with all the timing, capital risk, and outcome uncertainty that implies. SFDR-103 covers this in detail; the executive summary version is in Section 6.

Panda's Innovation Footprint Today

§ 04

Panda's pipeline in 2023–2026 is more substantive than its public profile suggests. Visible artifacts:

2023 • FORMAT Panda Home prototype Dripping Springs, TX • May 2023 Cultural-heritage interior, ~15% smaller dining room, expanded BOH, immersive drive-thru pictograms, enhanced digital pickup zone. Three years post-launch, no public expansion narrative.	2026 • FORMAT North Platte new format North Platte, NE • March 2026 Freestanding, drive-thru + dine-in hybrid, expanded kitchen footprint. Outcome data not yet disclosed.	2024 • SMART BUILDING GridPoint deployment ~2,500 US locations • 18-month rollout IoT energy management based on a 200-store pilot. 15–25% energy reduction, 3–5 year payback per industry-standard assumptions.
ACTIVE • VOICE AI SoundHound voice ordering Drive-thru • 10K+ locations ~85% standalone accuracy; ~95% on human + AI hybrid in industry benchmarks.	R&D • WOK Panda Auto Wok (PAW) Internal program • \$200M+ signal Specific deployment configuration not public. The test kitchen is the validation venue.	ACTIVE • BEVERAGE Tea Bar integration 39+ locations and growing Beverage-led footprint extension. Standalone unit economics not yet disclosed.

A reasonable read is that ~\$500M–\$1B of value creation is in flight across these initiatives. None of them are nothing. None of them are coordinated against each other on a stated cadence. That last sentence is what the team you are building solves.

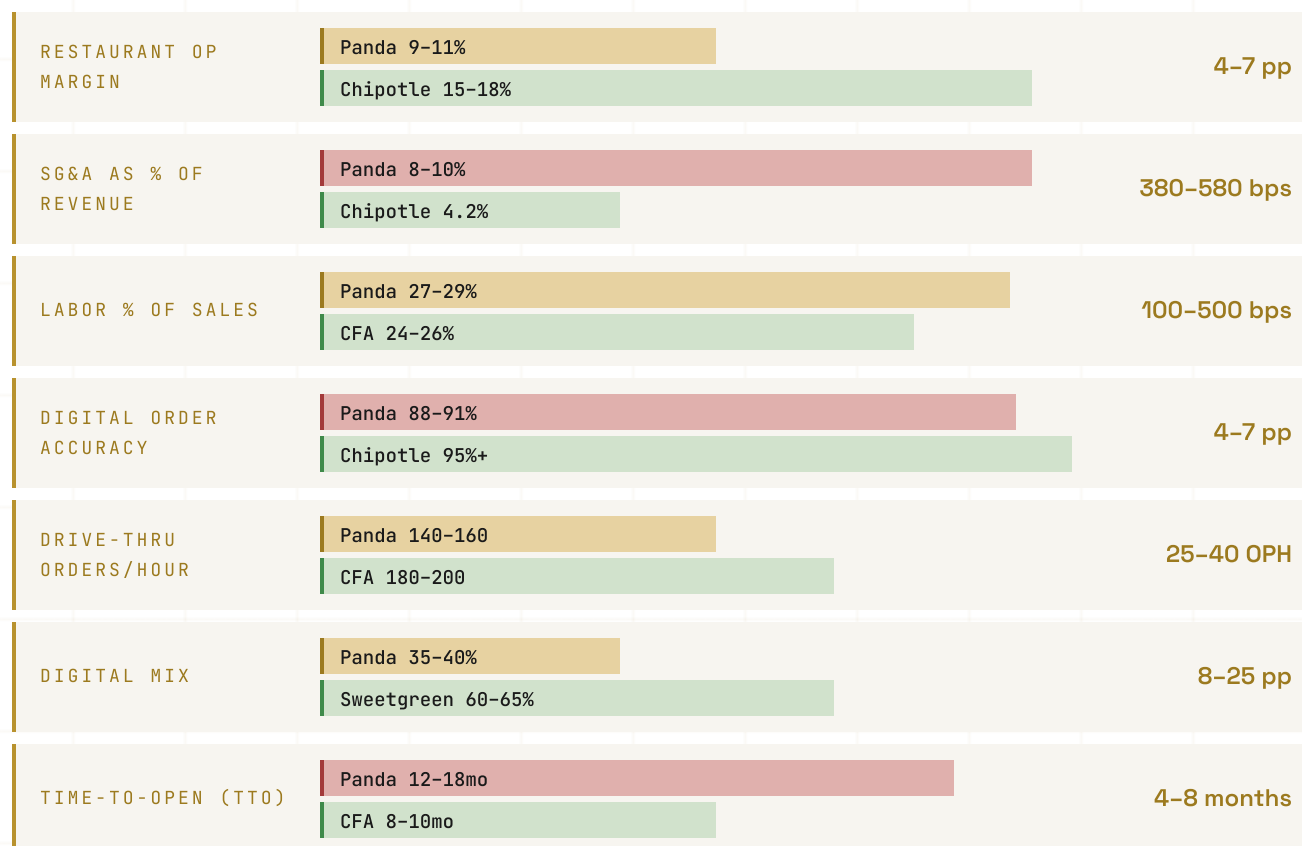

Ownership map (from public evidence + DR-03)

Three of these domains have clear owners. Three have ambiguous or implicit ownership. Two are cross-functional with no governance home. The unowned cells are the dependencies the team is being asked to coordinate.

DOMAIN	APPARENT OWNER	CONFIDENCE
Store format & design	James Ku (CDO)	High
Real estate / pipeline	James Ku (CDO)	High
Smart building / facilities	Supply Chain VP	High
Kitchen / BOH ops	COO Jeff Wang (likely)	Medium
Digital ordering / app	Unnamed CTO or EVP Digital	Medium
Voice AI (drive-thru)	Vendor-led with ops partner	Medium
Menu innovation	Scattered, no clear owner	Low
Wok automation / PAW	Internal R&D, leadership unclear	Low

The KPI Gap Map

The full KPI table is reproduced in Appendix A. The summary view, isolated to gaps that materially shape the innovation portfolio:

The pattern is consistent: Panda is competitive on absolute scale and digital penetration, lagging on cost structure and operational fidelity, conservative on growth velocity. None of the gaps individually are catastrophic. Several together define the addressable margin pool the team is being asked to capture.

A useful disaggregation: structural (very hard to close) vs. operational (closable). Structural is most of SG&A — the 100% company-operated model is a deliberate brand-control choice; that is not innovation's problem to solve. Operational is everything else, and it is large.

Where the dollars concentrate

Five gaps explain ~\$200–300M of annual addressable margin in pilot-realistic windows, with longer-horizon stretches reaching \$500M+ on growth velocity.

\$30–40M

Labor productivity

~\$100M if fully closed, \$30–40M realistic in 24-month pilot-to-scale. Source-of-gap is workflow + role design + peak-hour play-calling — not headcount. Validated peer playbook: Starbucks Siren Craft + Chipotle digital makeline. (DR-01, DR-05)

\$80–135M

Digital order accuracy

Largest fixable opportunity. Cause is the kitchen translation layer — POS → KDS → makeline → bag — not technology. Peer playbook: Chipotle dedicated digital makeline; Taco Bell Defy ghost kitchen format isolation. (DR-04)

\$5–15M

Drive-thru throughput

Per hundred high-volume units. CFA dual-lane + handheld order-takers + pull-forward zones (~150 cars/hr peak). Mobile channel segregation drops mobile wait times ~30%. (DR-08, DR-09)

\$50–100M

Digital mix expansion

If mix moves 42% → 50%+ over 36 months. Two constraints: digital fulfillment infrastructure and loyalty platform leverage. (DR-02, DR-03, DR-04, DR-07)

\$5–7M

Construction velocity

Per year at the current 123-unit cadence. Modular + AI scheduling compresses 30–40% of TTO at +2% per unit capex. (DR-12)

The remainder of the \$795M–\$1.34B portfolio sits in second-tier problems: kitchen automation roadmap, format innovation, GridPoint extension into predictive maintenance, franchisee transparency model, governance tightening.

The Seven Binding Constraints, Ranked

§ 06

The constraint ranking organizes the same evidence as the gap map but answers a different question — not "where is the dollar value" but "what stops the dollar value from being captured." The two views are complementary; the constraint view is more useful for character design.

01

STRUCTURAL · PARK

SG&A cost structure

Innovation cannot solve this. 100% company-operated model + family governance overhead. The right escalation is to CFO conversation; restaurant-level margin is the lever this function moves.

02

OPERATIONAL · HIGHEST PRIORITY

Digital order accuracy

Single-fiscal-year achievable. Capex envelope: \$200K–\$400K per high-volume unit for a dedicated digital makeline; \$3–5M total at top 10–15 stores. Path: SOP redesign at zero capex first, capex deployment second.

03

OPERATIONAL

Labor productivity

Wok cooking is intrinsically labor-intensive. Workflow redesign reclaims the first 1.5 pp; automation reclaims the next. ~140% wok-chef turnover compounds the cost (\$27–39M/yr replacement). Pre-prep batching, ergonomic deck redesign, sauce-prep protocols reclaim 100–140 bps with zero capex.

04

R&D · UNSOLVED

Kitchen automation (wok)

Honest target for any near-term pilot: 5–12% sustained, 15% stretch. Vendor claims above this number are unverified at commercial scale. PAW investment signals the choice has effectively been made; the test kitchen converts that choice from a procurement bet to a measurement program.

05

OPERATIONAL

Construction velocity

Solvable inside the team's scope. CFA at 8–10mo TTO is the right benchmark. A "compressed open" protocol piloted in 3–5 high-velocity markets (TX, CA, CO) with measurement against baseline cohort is the clean path. (DR-12)

06

FORMAT

Format conservatism

Panda Home and North Platte are good incremental designs. Neither is a frontier format. Dual-lane drive-thru (+16% throughput at CFA), vertical kitchen stacking (CFA Elevated, 2–3x throughput at compressed footprint), ghost-kitchen-adjacency (Taco Bell Defy) are the frontier moves.

07

OPERATIONAL

Kitchen execution fidelity

Connects directly to constraint 02. The translation problem (digital order data → KDS → makeline → bag) sits at the intersection of digital, operations, and store design. Two patterns: dedicated digital makelines (Chipotle, Taco Bell Defy); shared makelines + KDS + computer vision (McDonald's, Agot AI, Vistry). Test kitchen running both side by side is the cleanest comparative study.

The Test Kitchen as Operating Mechanism

§ 07

A test kitchen is not the only way to validate operational change. The peer set offers four credible mechanisms, each with a specific failure mode:

MECHANISM	COST SHAPE	CYCLE	CLEANEST CAUSATION?
Embedded pilot stores (Chipotle pre-Hyphen, Sweetgreen Infinite Kitchen)	Lower capex, higher live-P&L risk	Slower	No
Acquisition-driven validation (McDonald's Apprentice / Dynamic Yield)	Capital-heavy	Fastest if target exists	Mixed
Centralized R&D facility (Tryer, Cultivate, Speedee)	Higher capex, decoupled from live P&L	Faster iteration	Yes
Vendor-led on-site pilots (the path PAW partly sits on)	Low Panda capex, high vendor dependence	Mixed track record	Mixed

For Panda's specific portfolio of three unsolved questions — wok automation, >97% digital accuracy, drive-thru throughput at wok-menu complexity — the centralized R&D facility is the only architecture that produces clean comparative data on all three simultaneously. The reason: two of the three (wok and drive-thru) have no validated peer model, and the third (accuracy) requires controlled instrumentation across the full order lifecycle.

The mechanism choice has knock-on effects. A test kitchen produces an operating asset (the facility), an organizational asset (the rotation pool of GMs cycled through), and a knowledge asset (kill-gate data and benchmark framework). All three transfer back into the operating business. The other three mechanisms produce one or two but not all three.

The three validation vectors

VECTOR 01 • R&D-GRADE Wok automation No peer validation. Original applied R&D. Honest target: 5–12% productivity lift. Stretch: 15%. Sunk cost if killed at Gate 3: \$500–800K	VECTOR 02 • PARTIAL PEER VALIDATION Digital order accuracy at high volume No peer sustains >97% at scale. Best-in-class CFA at ~96–97%. Honest target: 95% at 40+ orders/hr. Stretch: >97%. Sunk cost if killed at Gate 3: \$300–500K	VECTOR 03 • STRONG PEER VALIDATION Drive-thru throughput CFA, Cane's, In-N-Out have proven the architecture. Honest target: 3:10 avg / 96% accuracy. Stretch: <3:00 / 97%. Sunk cost if killed at Gate 3: \$400–700K
---	--	--

Aggregate worst case if all three vectors are killed: \$1.2–2.0M. Within the PAW R&D envelope; not catastrophic at enterprise scale, but to be named in the ROI conversation rather than discovered after the fact.

Capex envelope, staffing, timeline

From SFDR-101 (peer test kitchen models) and SFDR-102 (greenfield QSR test kitchen capex/staffing/timeline benchmarks):

FOOTPRINT	3,500–5,500 sqft	Consistent with Chipotle Cultivate scope
BUILD-OUT COST	\$1.65M–\$4.15M	Hybrid (Scope C, recommended): \$2.25–2.85M

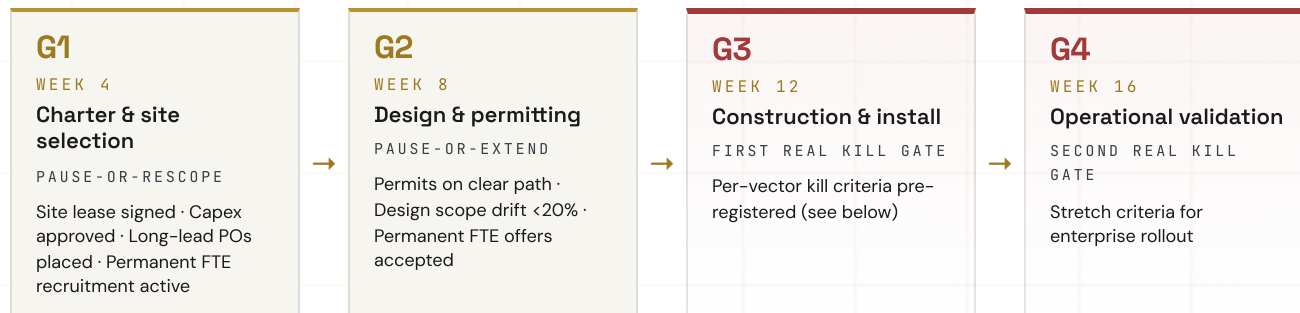

PERMANENT FTE	2.5–3 (lean) to 6 (peer norm)	Lean target consistent with single-shot validation budget
OPERATOR ROTATION	\$60–90K / 6mo cycle	2–3 store GMs on 2-month secondments
VENDOR ON-SITE SUPPORT	\$150–300K	Wok automation + KDS vendors; not in main capex envelope
CONTROL-STORE INSTRUMENTATION	\$150–250K	3 comparison stores, instrumentation only
TOTAL ALL-IN (SCOPE C)	\$2.61M–\$3.49M	Including rotation, vendor support, controls
TIMELINE	6–7 months	Aggressive vs. peer norm of 8–14 months

The largest capex line item, by SFDR-102 line-item benchmarking, is not equipment — it is drive-thru civil work (paving, canopy, menu boards, site egress), which can absorb \$400–800K. Equipment is the second-largest, with custom wok robotics (12–26 week lead time) on the critical path. A Phase O Gate 1 at Week 4 implies long-lead equipment orders by Week 2 at the latest.

Permitting is the silent variable. California is the slowest state for ground-up commercial restaurant permits (14–20 weeks); Texas and Arizona are fastest (8–12 weeks). A test kitchen near Rosemead is logistically ideal but permit-costly; a Las Vegas / Phoenix / Austin location accelerates permitting by 4–8 weeks at the cost of HQ proximity.

Kill Gates: Pre-Registered Failure Criteria

The single most important architectural choice in a test kitchen is whether the gates are advance gates or kill gates. Advance gates ask "is the project ready to move forward." Kill gates ask "has the project failed clearly enough that we should stop." The peer evidence — Starbucks Tryer's 60%+ kill rate at the regional pilot gate; Chipotle's pilot waves that kill more concepts than advance — is unambiguous: kill gates produce velocity, advance gates produce drift.

Per-vector kill criteria (G3 / G4)

VECTOR	G3 KILL (WEEK 12)	G4 KILL (WEEK 16)	IF KILLED
Wok	<5% lift OR >10% downtime OR safety incidents >2	<5% sustained, >10% downtime	Disable PAW bay; continue with commercial wok range; capture learnings for internal R&D
Accuracy	Sustained <93% at 40+ orders/hr	<93% at any peak	Pause integration; revert to baseline KDS; separate effort on translation layer
Drive-thru	Avg order time >3:15 at peak	>3:15 sustained at peak	Review architecture assumptions; rescope before next phase

If all three vectors clear stretch criteria, recommend full enterprise rollout program (Phase 5, separate scope). If one fails but two succeed, phase rollout of successes; kill or R&D-pivot the failure. If two or three fail, the test kitchen has done its job — the wrong investments are not made at scale, the learnings are captured, and the next round of bets is better-informed.

The governance that makes pre-registered kill criteria credible is not technical — it is political. Pre-registered criteria are visibly posted at the test kitchen site office. Gate decisions are made on data, not anecdote. The room making the call includes the program lead, the rollout sponsor (a designated peer in the operating function whose stores will receive the rollout), you, and a CFO representative. Quarterly board visibility on gate decisions ties the test kitchen back into the enterprise capital plan.

Team Architecture

§ 09

The team you are standing up has three jobs: run the test kitchen, coordinate the portfolio of innovation initiatives across digital / kitchen / construction / smart building, and produce data clean enough that capital allocation decisions get made on evidence rather than instinct. The structural questions are what the team contains, in what order it gets staffed, and how it gets traction on dependencies that sit outside the CDO mandate.

The capability mix

Five capabilities, ranked by hire sequence. Each is named for what it does — not for whom it reports to.

01

Program leadership

Owens the portfolio cadence, the gate decisions, the kill criteria, the quarterly readout. The central role; every other capability serves the program.

PERMANENT — HIRED FIRST

02

Kitchen / ops embed

Owens wok-side validation; partners with the operating function on the data path from cook line to bag handoff. Field operator background required.

PERMANENT — TEST KITCHEN GM + KITCHEN DIRECTOR

03

Digital fluency

Owens the accuracy program, KDS / POS / makeline integration, order-lifecycle instrumentation. Partners with the digital function rather than duplicating it.

FRACTIONAL OR CONTRACT THROUGH 2026

04

Construction / format extension

Already inside your team. The question is whether to add capacity or rebalance the existing roster against the test kitchen build-out plus the dual-lane drive-thru retrofit pilot.

EXISTING — RE-ALLOCATE OR AUGMENT

05

Data and measurement

Owens instrumentation across the test kitchen and three control sites. Statistical rigor matters here; this is the role most often underspecified at peer functions.

FRACTIONAL OR CONTRACT THROUGH 2026

Permanent versus fractional staffing

Some of these capabilities are permanent hires from day one. Others can be fractional through 2026 with a 6 to 12-month re-evaluation.

ROLE	FORM FACTOR	COMPENSATION ENVELOPE
VP / Head of Ops Innovation	PERMANENT	\$200–300K base + bonus
Test Kitchen GM	PERMANENT	\$130–180K + bonus
Test Kitchen Kitchen Director	PERMANENT	\$110–150K + bonus
Data lead	FRACTIONAL / CONTRACT THROUGH 2026	\$15–20K monthly fractional, or \$140–180K permanent
Strategy / portfolio chair	FRACTIONAL 6–12 MONTHS	\$50–75K monthly

The fractional pattern matters for two reasons. First, it preserves optionality on roles whose long-term scope is genuinely uncertain — the strategy chair role can be auditioned for two quarters before committing to a permanent shape. Second, it accelerates time-to-value: a fractional senior brings the playbook and the network on day one, where a permanent search would put the role in seat 4–6 months later.

Cross-functional traction without owning every function

A team inside the CDO mandate drives change on dependencies in digital, kitchen ops, and supply chain through three mechanisms — none of which require those functions to report into yours.

MECHANISM 01

Steering rhythm

Quarterly portfolio review attended by the digital lead, the COO's office, the supply chain VP, and a CFO representative. You chair because the team is yours; the agenda is jointly authored so each function commits to its piece of the portfolio in the room.

MECHANISM 02

Shared instrumentation

When the test kitchen ships data on accuracy, throughput, or labor productivity, that data lives in the operating functions' KPI dashboards — not in a CDO silo. Your team produces the measurement; the operating function takes the credit when the number moves. The single most important norm to set early.

MECHANISM 03

Sponsor pairs

For each major initiative (digital makeline pilot, drive-thru retrofit, GridPoint predictive maintenance extension), pair a member of your team with a named sponsor in the operating function. They co-own the rollout — your team brings the validation, the sponsor brings the operational authority to scale.

Build-out sequence

MONTHS 1–3

Stand-up

- Program lead in seat (fractional bridge if permanent search is still running)
- Test kitchen GM and Kitchen Director identified, offers extended
- Data lead retained on contract
- Sponsor pairs named for each major initiative

MONTHS 4–6

Operate

- Test kitchen permanent staff onboarded
- First quarterly portfolio review completed
- First three control sites instrumented

MONTHS 7–12

Decide

- First kill-gate decisions made on test kitchen vectors
- Second quarterly portfolio review
- Decision on fractional-to-permanent transition for the strategy chair role

What this team looks like at month 12: a permanent core of 4–5 staff plus a fractional or contract layer, a quarterly steering rhythm with three other function heads, three vectors of test kitchen data with pre-registered kill criteria, and a portfolio of named-sponsor initiatives where each rollout has a co-owner inside the operating function that will absorb it.

A 90-Day Action Map

These items do not require a search firm, a SOW, or an external advisor. They are the things that, executed cleanly inside Panda's existing org, produce the data needed to commit on the test kitchen and on the team build-out.

WEEKS 1–4

Visibility

- **Stand up an internal cross-functional readout**, weekly, with you, the COO's office, the CTO/digital owner, the supply chain owner, and a CFO delegate. Standing agenda: portfolio status across the four largest dependencies. Goal is mapping, not deciding.
- **Commission a digital order accuracy baseline by channel** (IP app, DoorDash, Uber Eats, Grubhub) at 50 representative units. Two-week measurement window. No capex. Input for the constraint-2 capex decision.
- **Audit the wok-chef turnover number** system-wide and at the top 200 high-volume units. Compare to industry benchmark. Input for constraint-3 economics.
- **Name a single owner** for each of the four unowned dependencies. The owner does not have to be a new hire; it can be an existing executive with the dependency added to scope.

WEEKS 5–8

Calibration

- **First Innovation Portfolio review** with the four dependency owners. Use the Section 4 KPI gap map as the dashboard. Single deliverable: ranked initiative list with owner, scope, measurable target.
- **Pilot the Starbucks Siren Craft "Peak Play Caller" role** at 3–5 high-volume Panda units. Zero capex. Measure peak-hour OPH delta over four weeks. Cleanest fast-validation of the Constraint-3 workflow lever.
- **Decide on test kitchen scope** (Scope A semi-automated, Scope B full robotics, Scope C hybrid). Recommended: Scope C. If proceeding, place long-lead equipment contingent POs.
- **Make the team architecture decision** on permanent vs. fractional roles, or commit to running the recommended pattern for two quarters and re-evaluating.

WEEKS 9–12

Commitment

- **If test kitchen confirmed:** file site permits (CA timing dictates Week 9 file date for a Rosemead-area site), sign site lease, finalize Phase O charter with kill gates pre-registered.
- **If team architecture confirmed:** identify and onboard the fractional strategy chair (or stand up the equivalent through your existing executive network). Permanent search for the program lead can run in parallel.
- **Publish the Panda Innovation Portfolio internally** — quarterly cadence, named owners, kill criteria, expected investment, expected return. The act of publication is half the value; it converts ambiguous ownership into accountable ownership.

What this does not require: a new external advisor. The ninety-day map is mostly internal calibration. The decisions get made by Panda. The data needed is mostly already inside the company; the visibility cadence is the new artifact.

Anti-Patterns: What Peer Failures Should Stop You From Building ^{§ 1.1}

Five things the comp set proves are wrong. Drawn from DR-01 through DR-14 and the SFDR-101–103 deep dives.

Do not build a venture-arm

Evidence: Walmart Store No. 8 (dismantled 2024). McDonald's IBM partnership (divested 2022).

Action: Embed innovation in the operating model; do not silo it. The test kitchen is decoupled from a live P&L for measurement reasons, but the rollout pathway is integrated into operations from day one.

Do not promise wok productivity lift above 15%

Evidence: Every peer that has tried makeline robotics has captured 5–15% sustainable productivity gain at scale. Chinese vendor claims of 25–40% wok productivity lift have zero verified commercial QSR deployments.

Action: A pilot targeting 5–12% lift with a 15% stretch is on-precedent. A pilot targeting >15% sells a number no peer has demonstrated.

Do not bundle automation capex with the accuracy program

Evidence: Chipotle's combined Autocado + Hyphen pilot (2023) had unclear attribution — which lever drove which metric.

Action: Three vectors at the test kitchen must be instrumented separately so causation is observable. Bundling makes the data unfalsifiable, which makes future capital allocation a faith argument rather than an evidence argument.

Do not run validation with fewer than three control sites

Evidence: McDonald's Siren validations and Chipotle's earliest Chipotlane prototypes both stumbled — single-unit results couldn't be cleanly attributed without a control cohort.

Action: One test kitchen + three instrumented Panda stores producing baseline data is the minimum credible architecture. \$150–250K instrumentation; no capex changes at the controls.

Do not run voice AI as a Phase 1 experiment at the menu board

Evidence: McDonald's voice AI (2019 Apprente, then 2022 Google Cloud reset) and Starbucks personalized recommendation (2019, deprioritized) are both cautionary.

Action: Panda already has SoundHound at scale; that is the level of deployment to maintain. Adding a wok-menu-complexity voice AI experiment burns budget on a problem the comp set has not solved.

The Decisions Only You Can Make

§ 1.2

Five questions whose answers shape the entire subsequent program. Each has a default if unanswered, and the default in each case is the lower-velocity path.

01

What is the CEO's appetite for the team you are building?

Every internal innovation function eventually needs CEO awareness — capital, cross-functional alignment, board visibility. The 100-day window after a CEO transition is when you can propose the team's mandate as a clear, time-boxed hypothesis rather than a vague capability addition. The more specific the propose-it-and-measure-it framing, the easier it is for the CEO to back without committing to a permanent restructure.

02

Corporate-only innovation, or franchisee-inclusive?

Panda is largely company-operated, which removes the franchise capital co-funding gates that constrain McDonald's (DR-13). The implication is velocity advantage. The implication for franchisee adoption — to the extent franchisees exist in the model — is that transparency and incentive alignment (PS-17 in the problem portfolio) become prerequisites. The default if unanswered is corporate-only — faster but smaller.

03

How aggressive is the automation appetite?

A Scope A semi-automated test kitchen (\$1.65–2.15M) and a Scope B full-robotics test kitchen (\$3.15–4.15M) signal different things to vendors, recruits, and the board. Scope C (\$2.25–2.85M hybrid) preserves optionality on PAW while still capturing the digital accuracy and drive-thru learnings cleanly. If the strategic intent is to lead the industry on wok automation, Scope C is correct. If the intent is to be a fast follower, embedded pilot stores are sufficient.

04

Will Panda close underperforming units, or commit to turnaround at all locations?

This question shapes the rollout architecture for any successful pilot. If willingness to close exists, innovation can target high-potential units only. If not, innovation must work at all maturity levels — harder, slower, less margin-accretive but produces a more resilient brand. Default is "no closures," the more conservative path.

05

How much capital can the team deploy in 2026–2027?

The portfolio of 20 problem statements ranges from zero-capex (workflow redesign, gate governance) to \$5–10M (test kitchen, dedicated digital makelines, dual-lane drive-thru retrofits) to \$50M+ (vertical-stack format pilot, ghost kitchen network, Tea Bar standalone economics). A \$5M annual envelope vs. \$20M vs. \$50M changes realistic 24-month scope by 4x.

These five answers are the inputs to program design. Three of them (#2, #3, #4) sit cleanly inside the CDO mandate as you have publicly framed it. Sequencing the five questions deliberately — answering the three you own first, then bringing the two CEO-dependent questions to the new CEO with a position rather than a question — is the lowest-friction path.

Innovation Lab — Top 5 Concepts

The five concepts below are drawn from a parallel innovation-workshop pass — roughly 30 candidate ideas, scored across labor impact, capex, throughput multiplier, and brand differentiation. The five featured here are the high-conviction physical and format moves where a CDO mandate maps directly to construction, kitchen design, and site decisions. Each is paired with a representative concept rendering — illustrative, not architectural. The full ranked workshop output (with second-tier concepts on inventory automation, predictive maintenance, ghost kitchens, voice AI, and others) is available on request.

TIER 1 • SCORE 4.1 • WOK AUTOMATION

Wok Automation 2.0 — Botinkit Integration

PROBLEM Kitchen labor is the binding constraint on growth. Wok-chef turnover is ~140% annually; wages have moved 30% in three years.

WHAT Next-gen Botinkit Omni-class wok robots execute entire recipes autonomously — measured ingredient dispensing, AI-optimized heat curves, consistent wok hei. Target: reduce kitchen staff from 8 to 3 per location with no compromise on the wok-fired brand promise.

WHY NOW Production-deployed in Asia. 30% ingredient loss reduction, 40% energy reduction, 2x throughput vs. manual. Panda's menu — Orange Chicken, Beijing Beef, Chow Mein — is structurally ideal: high-volume, repeatable recipes.

FIRST MOVE Visit Botinkit factory in Shenzhen; run a 5-store pilot with Omni systems instrumented against control sites.

TIER 1 • SCORE 4.2 • CONSTRUCTION VELOCITY

Modular Restaurant Kit

PROBLEM Construction is too slow and too expensive for the growth target. Traditional builds take 6 months; at 123 stores per year, weeks compound into millions.

WHAT Prefab restaurant modules (kitchen pod, dining pod, drive-thru pod) manufactured off-site and assembled in 60 days. Kitchen module arrives with all equipment pre-installed and tested. Site work runs in parallel with module fabrication, not in series.

WHY NOW Modular construction is 30–50% faster and 20–30% cheaper at scale. CFA, Starbucks, and Marriott have proven the architecture; no major QSR chain has standardized it. CFA's 8–10 month TTO benchmark is achievable inside this approach.

FIRST MOVE Partner with a modular construction firm (Falcon, Guerdon, or RAD). Design the kitchen-pod prototype. Test full assembly on one greenfield site.

TIER 1 • SCORE 4.4 • FORMAT RETROFIT

Digital Lane Splitter

PROBLEM The box was designed for dine-in, but 42% of revenue is digital. Mobile orders queue against walk-in customers on the same line; both channels lose.

WHAT A second drive-thru lane dedicated to mobile-app pickup only. Pre-paid orders, sub-60-second handoff, no menu-board interaction. Retrofit into existing high-volume locations; engineered into all new builds.

WHY NOW Chipotle Chipotlane proved the architecture (700+ stores, 10–15% sales lift). No Asian QSR chain has done this. First-mover in the category.

FIRST MOVE Identify 20 locations with the highest digital-order share. Design the retrofit package. Pilot at 5; measure throughput, accuracy, and incremental sales.

TIER 2 • SCORE 3.9 • NEW FORMAT

Panda Counter — Japanese-Inspired Small Format

PROBLEM No format exists between "full Panda Express" and "food-court kiosk." Urban rents are prohibitive for full-format stores; dense markets are under-served.

WHAT 800 SF counter-only Panda. U-shaped counter seating (12–16 stools). Ticket-machine ordering at entry. Visible wok station behind the counter as kitchen theater. Self-serve water and tea. No tables. Twelve-minute average visit.

WHY NOW Yoshinoya, Matsuya, Sukiya, and CoCo Ichibanya have run this model at scale across 5,000+ Japanese locations. Build cost lands at ~40% of full-format. No US QSR chain has adopted the architecture; first-mover advantage in dense urban cores, transit hubs, food halls.

FIRST MOVE Visit Tokyo for an operations study (Yoshinoya, CoCo Ichibanya). Design a Panda Counter prototype. Test in one dense urban market.

TIER 2 • SCORE 3.7 • FRONTIER FORMAT

Vertical Kitchen Concept

PROBLEM In high-AUV urban markets, real-estate availability is the binding constraint on expansion. Conventional footprints don't fit; vertical is the only path.

WHAT Kitchen stacked above ground level with dual drive-thru lanes passing underneath. 2–3x throughput on the same land footprint. Modeled on CFA Elevated (first units 2023–2024) and Yum China RGM 3.0.

WHY NOW CFA proved the architecture (10–15 vertical units/year by 2025). No Asian QSR chain has followed. In high-land-cost markets (CA, NY, TX urban cores), vertical compresses per-unit land cost 30–40% while multiplying throughput.

FIRST MOVE Identify 5 highest-performing urban Panda locations where lot size constrains throughput. Commission an architecture study for vertical adaptation.

The remaining workshop output covers the second-tier concepts: ghost-kitchen insertion, demand-responsive labor scheduling, drive-thru voice AI, vertical kitchen variants, predictive equipment maintenance, trade-area cannibalization modeling, sustainable build standard, central commissary model, recipe intelligence platform, an international export kit, order-ahead lockers, and the Walmart-outparcel + DoorDash co-branded virtual-kitchen partnership angles. All are documented with scoring, evidence, and first-move detail; available on request.

What Was Examined, What Wasn't

§ 14

This synthesis represents 14 deep research threads (DR-01 through DR-14) and 3 supplementary focus dossiers (SFDR-101 on peer test kitchen models, SFDR-102 on greenfield QSR test kitchen capex/staffing/timeline benchmarks, SFDR-103 on peer learnings mapped to Panda's binding constraints). Combined source corpus: 480+ cited public sources, ~600 pages of internal working notes.

Source corpus map

Thread	Topic	Sources	Primary Contribution
DR-01	Ops innovation at Walmart, Starbucks, McDonald's	43	Big Three operating models; Store No. 8 failure mode
DR-02	Ops innovation at Chick-fil-A, Chipotle, Taco Bell, Sweetgreen, Domino's	40	Peer comp set; franchise innovation adoption patterns
DR-03	Panda's current decentralized footprint	35+	Ownership map; absence of unified cadence
DR-04	Digital order accuracy root causes	35+	Channel-by-channel error decomposition; peer solution patterns
DR-05	Labor productivity, automation, process redesign	42	Workflow lever evidence; turnover cost economics
DR-06	Kitchen automation state-of-the-art (wok, makeline)	35+	Wok unsolved finding; viable vs. vaporware vendor map
DR-07	Panda financials and KPI benchmarks	30+	Gap quantification; addressable margin pool math
DR-08	Format innovation 2025–2026 frontier	38	Dual-lane, vertical stacking, ghost kitchen evidence
DR-09	Drive-thru innovation at scale	32	CFA, Cane's, McDonald's benchmarks; SoundHound performance
DR-10	Smart building, facilities tech	114	GridPoint extension into predictive maintenance + waste tracking
DR-11	Site selection, AI trade area analysis	30+	Format capital efficiency support
DR-12	QSR construction pipeline, modular, speed-to-open	25+	TTO compression math; CFA control benchmark
DR-13	Cherng family governance; recent CEO transition	30+	Governance constraint analysis; lite franchising appetite
DR-14	Ops innovation hiring market	30+	Fractional-to-permanent leadership patterns
SFDR-101	Peer test kitchen models	25+	Tryer / Cultivate / Speedee benchmarks
SFDR-102	Greenfield QSR test kitchen capex/staffing/timeline	15+	Cost-per-sqft, FTE ratios, equipment lead times
SFDR-103	Peer learnings mapped to Panda's binding constraints	15+	What-not-to-do list; per-vector kill criteria

What was not examined

The corpus is public-source. Material that is non-public, non-discoverable, or operationally specific to Panda was not within scope of this research cycle:

- PAW current capability and roadmap. Internal Panda program; status, capex deployment to date, and validation milestones are non-public.
- Panda labor cost detail by station and by geography. Inferred from public proxies (DR-05, DR-07).
- Panda Home + North Platte unit economics. No public expansion narrative; North Platte too recent for outcome data.
- Cherng family-level decision velocity on innovation governance. Inferred from DR-13 and 2026 CEO-transition reporting.
- Franchisee-side data on innovation adoption appetite. Not public; covered as a knowledge gap in the synthesis library.
- Specifics of any active vendor relationships beyond what is publicly disclosed (SoundHound, GridPoint).

Open questions only Panda can answer

Sixty-two open questions are catalogued in the knowledge-gap synthesis. The ten that most materially shape the analysis above:

1. Panda's baseline crew turnover rate by role cohort, and its correlation with order accuracy and customer satisfaction.
2. Panda's unit economics by format, and the cash-on-cash ROI threshold for innovation investments.
3. Whether there is a centralized technology roadmap, or if digital infrastructure is fragmented; current KDS vendor and deployment status.
4. Panda Home unit economics — strategically viable format or pilot dead-end.
5. Board risk tolerance for ops innovation pilots; prior failed innovation mandates that shape current constraints.
6. Permanent ops innovation role architecture; appetite for a fractional bridge.
7. Franchisee visibility into unit economics; appetite for operational changes requiring training or process redesign.
8. Capital constraints (annual capex for tech, equipment replacement cycle, franchisee capex appetite) and how these limit kitchen automation, drive-thru dualing, GridPoint extensions.
9. SG&A breakdown by function; whether there are corporate efficiency opportunities that could fund innovation.
10. How order accuracy is currently measured (by channel, location, menu item); executive visibility into the gap between digital placement and delivered accuracy.

The open questions are worth their own conversation. None of the recommendations in this synthesis change materially based on the answers — but the timeline and the capex envelope of any committed program will.

Appendix A — KPI Benchmark Table

Metric	Panda	Chipotle	CFA	Taco Bell	Sweetgreen	McDonald's	Starbucks	Dominio's
AUV (TTM 2024)	\$1.6M	\$2.6M	\$2.2M	\$1.2M	\$1.5M	\$2.3M	\$2.0M	\$2.4M
Restaurant op margin	9–11%	15–18%	14–16%	10–12%	2–4%	12–14%	18–20%	16–18%
Labor % of sales	27–29%	26–28%	24–26%	26–28%	32–35%	25–27%	23–25%	14–16%
Capex per unit	\$450–550K	\$600–700K	\$400–450K	\$320–380K	\$800K–1M	\$1.5–2M	\$700–800K	\$1.2–1.5M
Payback period	3.5–4.5y	3–4y	2.5–3.5y	4–5y	5+y	6–8y	4–5y	3–3.5y
Digital mix	35–40%	50–55%	45–50%	42–48%	60–65%	48–52%	n/a	n/a
Order accuracy (median)	91–93%	94–96%	94–96%	92–94%	93–95%	91–93%	n/a	n/a
Digital order accuracy	88–91%	95%+	94%+	92–94%	94–96%	90–92%	n/a	n/a
Drive-thru OPH	140–160	120–140	180–200	150–170	n/a	160–180	n/a	n/a
Unit growth (3y CAGR)	3–4%	7–9%	5–6%	4–5%	8–10%	1–2%	n/a	n/a
Same-store sales	4–6%	8–12%	5–7%	3–5%	10–15%	2–4%	n/a	n/a
Innovation maturity (1–5)	2–3	4–5	4	4	3–4	5	4–5	5

Sources: DR-04, DR-05, DR-07, DR-08, DR-09. Maturity rating is a qualitative composite of breadth-of-formats × tech-integration × innovation-cadence. Estimates use industry medians where Panda data is non-public.

Appendix B — About This Research

§ 16

The corpus underlying this whitepaper was built between April 11 and April 24, 2026, in two phases. Phase 1 (April 11–16) produced the company-and-people baseline that preceded the April 16 introductory call. Phase 2 (April 17–24) produced the 14 deep research threads and 3 SFDR focus dossiers this synthesis draws from.

Each deep research thread was scoped to a specific operational question, executed against public sources (SEC filings, earnings calls, investor presentations, trade-press reporting, vendor disclosures, academic publications, regulatory filings), and validated against at least two independent sources per material claim. Every paragraph in this whitepaper has a source thread it can be traced back to.

The 480+ source count understates the actual research volume. It counts cited sources only, not background reading, vendor interviews, or peer-company artifact analysis. The internal working corpus is approximately 600 pages of structured notes, problem-statement writeups, KPI benchmarks, and synthesis documents.

If any specific section above produces a question that the synthesis does not address, the underlying material almost certainly does. The path to it is the source-thread map in Section 12.

End of synthesis. April 30, 2026.
